

*Support for when you suddenly became the one taking care of everything.*

Be10X AI Generalist Hackathon — Problem Statement & Solution

---

## 1. The Problem

When a loved one — a parent, grandparent, sibling, or spouse — becomes sick or begins to decline with age, the people around them are often thrust into a caregiving role overnight, with no medical training and no one to guide them. This is one of the most common and least-discussed situations in Indian households, and it quietly overwhelms people for months or years.

In practice, this shows up as a series of small, high-stakes moments a caregiver has to navigate completely alone:

- Reading a prescription or medical report full of abbreviations and medical shorthand, with no idea what it actually means.
- Noticing a change — confusion, tiredness, a new symptom — and not knowing whether it's a minor thing or something that needs urgent attention.
- Carrying the emotional weight of caregiving — guilt, exhaustion, grief for their old life — with no space to express it honestly.
- Losing track of what's been happening over days and weeks, with no organized record to refer back to or share with a doctor.

Right now, the only real options are: spend 45–60 minutes anxiously searching the internet, call a doctor for something that may not warrant it, or simply guess. None of these are good enough for something this important.

## 2. Who This Is For

Anchor is built for anyone who has suddenly become a caregiver for a loved one — a parent, spouse, sibling, grandparent, in-law, or close friend — without any prior medical training. It is specifically not built for trained or professional caregivers, who already have the knowledge Anchor is designed to provide.

## 3. The Solution

Anchor is a web app with four connected features, all built around one question: "I'm suddenly responsible for someone's care and I don't know what I'm doing — help me right now."

### 3.1 Report & Prescription Explainer

The caregiver uploads a photo of a prescription or medical report, optionally paired with a specific question (e.g. "what does q.i.d. mean?" or "is this eGFR level bad?"). Gemini reads it and explains, in warm plain language, what condition it relates to and what each medicine is for, then produces a clear structured medication schedule the caregiver can check off. It separately surfaces the doctor's own follow-up red flags — the specific "return immediately if X" thresholds from the report — so they're never buried inside a wall of text, along with general safety precautions and a few suggested questions to ask at the next visit. Tested successfully on a real hospital discharge summary and a multi-condition outpatient prescription, including correctly extracting numeric red-flag thresholds (e.g. specific blood pressure and blood sugar limits) and decoding medical shorthand (e.g. "1-0-1" dosing notation, and a text-only question about "q.i.d." dosing answered accurately without needing a new document upload).

### 3.2 "Is This Normal?" Symptom Checker

The caregiver describes a symptom or change they've noticed in plain words, along with how long it's been happening, and can optionally attach a photo for anything visible like a rash or swelling. Gemini responds with a clear urgency tier — Monitor at home, Call the doctor soon, or Seek care now — along with plain-language reasoning and 2–3 practical next steps. In testing, this correctly classified a mild, non-urgent symptom as safe to monitor; correctly flagged gradual fatigue and appetite loss as worth a same-day call (citing plausible causes like dehydration or infection); and correctly flagged chest pain, breathing difficulty, and stroke-like symptoms as immediate emergencies — each paired with India-specific emergency guidance (112 / 108). It also correctly avoided being reassured by ambiguous framing, defaulting to the more cautious tier when a symptom description included a minimizing phrase (e.g. "might just be low blood sugar").

### 3.3 A Space to Talk It Through

Caregiving is exhausting and often lonely, full of feelings people don't feel comfortable voicing to family. This gives the caregiver a private space to express how they're actually doing, with Gemini responding with warmth calibrated to match what was actually shared — light and brief for an ordinary update, warmer for common caregiver guilt or exhaustion, without treating either as a crisis. When testing showed sustained signals of isolation (explicitly going on "for months," barely seeing anyone, questioning their purpose), the app appropriately and gently surfaced real support resources — Tele-MANAS and the KIRAN helpline — without over-triggering on ordinary venting.

### 3.4 Care Log

Every successful report explanation and symptom check is automatically saved to a running, reverse-chronological timeline — no extra effort from the caregiver, and no additional AI calls required. Symptom entries are colour-coded by urgency so a caregiver (or a doctor they're sharing it with) can scan weeks of history at a glance. Report explanations can also be downloaded as a clean PDF to keep or share.

### 3.5 Caregiver Breathing Anchor

Caregiving takes a toll on the caregiver too, not just the person being cared for. The home screen offers a short, guided 60-second breathing exercise (a 4-7-8 calming sequence) the caregiver can use any time they need a moment to reset. Tested and working.

## 4. Why This Needs AI

Every report, prescription, symptom, and emotional situation described to Anchor is different — there is no fixed list of answers to look up. The AI has to genuinely read and reason about each specific situation:

- Interpreting inconsistent medical shorthand and multi-condition prescriptions correctly, including conditional follow-up instructions tied to specific numeric thresholds.
- Weighing symptom descriptions — including deliberately ambiguous or minimizing ones — to arrive at a calibrated urgency level, rather than matching against a fixed keyword list.
- Responding to open-ended emotional expression with a tone that matches the actual weight of what was shared, and recognising the difference between ordinary caregiver guilt and genuine sustained distress.

A rule-based tool, template, or simple keyword search could not perform any of these — this is real, meaningful AI leverage, not an AI feature bolted onto standard software.

## 5. Practical Impact

Understanding a confusing medical report, which normally takes a caregiver 45–60 minutes of anxious searching and guessing, now takes under 2 minutes. Deciding whether a new symptom needs urgent attention — a decision many caregivers currently get wrong in both directions, panicking over something minor or missing something serious — now comes with a clear, calibrated answer in seconds.

## 6. Tools Used

Built using Google AI Studio (no-code), powered by Google's Gemini model for all reasoning, explanation, and conversational features. Claude was also used as part of the development and testing process.
